

IN THE CLAIMS:

Please amend the claims as follows:

1. (Currently Amended) A message filtering circuit used in a distributed control system in which a plurality of nodes are connected to a transmission line, each node controlling components in this node and transmitting messages to other nodes, said message filtering circuit comprising:

a message storing part of taking-in and storing each of said messages transmitted on said transmission line, each of said stored messages including ~~an identifier indicating a~~ at least one message-sending node, and an identifier indicating a message-receiving node or non- ~~designation of a message-receiving node~~ and a condition information accompanying said data;

a registration part for registering data of message-receiving conditions in advance;

at least ~~one~~ two comparison part parts for comparing ~~said identifiers of said condition-~~ identifying portions with said data of message-receiving conditions registered in said registration part a condition data which is registered in advance in said registration part and said identifier stored in said message; and

at least one received-message storing part for storing a taken-in message according to results of said comparison-processing performed in said at least one comparison part and for sending said stored message to an external circuit.

2. (Original) A message filtering circuit according to claim 1, wherein a digital signal processor is used for said comparison part.

3. A message filtering circuit according to claim 1, wherein a programmable logic circuit is used for said comparison part.
